DUAL-PANE UI ARCHITECTURE

- Layout Strategy: The screen is divided into two main sections using a flexbox-based .container.
- The Branding Side (Left):
 - Visual Depth: A background image of a building is combined with a blue overlay using background-blend-mode: multiply and an opacity: 0.3 to ensure the white text remains legible.
 - Trust Building: Includes a quote from Vincent Obi to give the banking interface a professional and established feel.
- The Interactive Side (Right):
 - Acts as a "Dynamic Portal" where the content changes based on user progress while the branding on the left stays consistent.

STEP 1 – ACCOUNT TYPE SELECTION

- Visual Feedback: The cards for "Individual" and "Business" respond to clicks.
- CSS Implementation: I used a `.card.selected` class that changes the border color to blue (`#1e62e1`) and adds a light blue background (`#f0f5ff`).
- JavaScript Interaction: The `selectCard(this)` function ensures that when one card is clicked, the `.selected` class is removed from others, making the choice clear to the user.

STEP 2 – PERSONAL INFORMATION & VALIDATION

- Data Collection: Gathers the user's Full Name and Email Address.
- Real-time Logic: I added "input" event listeners in script.js so the website checks for errors as the user types.
- Error Handling:
 - If the name is less than 3 characters, the showError() function dynamically creates a red error message under the input box.
 - The email is validated using a Regular Expression (Regex) to ensure it follows the user@domain.com format.

STEP 3 — BANK VERIFICATION (BVN)

- Visual Status: As shown in image_a37992.png, this step features a progress indicator "STEP 03/03" and a "Bank Verification" label.
- Security UI: Added a green checkmark icon inside the input box to visually confirm a successful entry.
- Strict Validation: The logic ensures the BVN is exactly 11 digits long using the test `/^[0-9]{11}$/`. If it doesn't match, the "Save & Continue" button will trigger an alert rather than submitting.

JAVASCRIPT STATE MANAGEMENT

- The `showStep()` Function: This is the "brain" of the navigation. It hides all steps by removing the `.active` class and reveals the specific step needed.
- Flow Control:
- `nextStep(n)`: Moves the user forward after validation passes.
- `prevStep(n)`: Allows the user to go back and correct info without losing data.
- Sign-In Bridge: A separate `goToSignIn()` function handles the transition to the "Welcome Back!" screen, providing a complete user journey from registration to login.

```
function nextStep(stepNumber) {  
    showStep(stepNumber);  
}  
  
function prevStep(stepNumber) {  
    showStep(stepNumber);  
}  
  
function goToSignIn() {  
    showStep("signIn");  
}
```

TECHNICAL HIGHLIGHTS & BEST PRACTICES

- Responsiveness: Included a `<meta name="viewport">` tag and used relative units (like `vh` and `%`) so the UI looks great on both desktops and mobile devices.
- User Guidance: Used `alert()` boxes as a final confirmation layer to tell the user "Form submitted successfully" or "Login successful".
- Clean Code: Organized the project into three distinct files (`index.html`, `style.css`, `script.js`) to keep the logic and design separated and maintainable.
